# SOUTHEAST NEW HAMPSHIRE WATER RESOURCES STUDY

# COMPARISON AND EVALUATION of EARLIER IDENTIFIED RESERVOIR SITES

DEPARTMENT OF THE ARMY
NEW ENGLAND DIVISION, CORPS OF ENGINEERS
WALTHAM, MASS.

**APRIL 1978** 

### NOTE

Some of the information contained in this report has been derived from data developed by the U.S. Department of Agriculture - Soil Conservation Service as part of the North Atlantic Regional Water Resources Study dated May 1972. The information has been updated to reflect present day costs and has been supplemented by on-site evaluation of each of the earlier identified surface water reservoir locations.

No attempt has been made to evaluate the feasibility of the reservoirs in the development of water supply alternatives to serve the region. The report merely presents the results of those investigations deemed appropriate for consideration of the potential water supply sources.

COMPARISON AND **EVALUATION** 0F EARLIER IDENTIFIED RESERVOIR SITES IN SOUTHEAST NEW HAMPSHIRE

Hayden, Harding & Buchanan, Inc.
Consulting Engineers

### **PURPOSE**

It was the purpose of this investigation to review sites proposed for surface supply reservoirs. The review encompassed making a survey of each site, insofar as roadway access permits, to determine site characteristics, developments and general impacts. Each site was evaluated on the basis of engineering, environmental, economic and social aspects.

Construction cost estimates were updated to an Engineering News Record Construction Cost Index of 2600 (Autumn 1977). Data used in establishing the estimates of cost were taken from information developed by the U.S. Department of Agriculture Soil Conservation Service made available by the Corps of Engineers.

It is understood that the information obtained and developed from this investigation is to be used in decision processes regarding near and far term planning. In order to facilitate that decision process, the information has been aggregated into a tabular display.

SUMMARY:
ASPECTS OF
RESERVOIR CONSTRUCTION

### ASPECTS OF RESERVOIR CONSTRUCTION

### General

Pursuant to Work Order No. 3 of Contract DACW 33-77-C-0066, Design of Miscellaneous Facilities and Related Work (1977-1978), Various Locations in New England; aerial and ground reconnaissances have been made of reservoir sites in <u>southeastern New Hampshire</u>. The particular <u>locations investigated</u> were forty-nine <u>sites</u> selected by the Soil Conservation Service (SCS) of the U.S. Department of Agriculture as a portion of the North Atlantic Regional (NAR) Water Resources Study. Data regarding the sizes, volumes, elevations, locations and yields of the various reservoirs were taken from information developed by SCS and made available by the Corps.

Since the depth of investigation possible under the auspices of this study was limited, many aspects of reservoir construction were analyzed on a qualitative rather than a quantitative analysis. Where permitted by the scope of work, quantitative results have been developed and presented. Quantitative results encompass such aspects as houses, barns, and businesses disrupted and roadway, railroad and utilities relocations.

### Distance to Areas of Need

The New England Division of the Corps of Engineers in a report upon "Estimated Demands and Resource Availability", dated July 1976, for the Southeast New Hampshire Water Supply Study, defined and estimated future municipal water requirements and present supplies. From these data, the report indicated municipalities where additional supply may be required. Existing Safe Yields, Demand and Deficits for Communities with Public Water Supplies, taken from that report, have been repeated in Figure 1.

For the purpose of establishing the distance to point of need from the reservoir being studied, this report has considered a point of need to be the major developed area of a town indicated to have an additional water requirement by the year 2020. Distances were measured along the shortest roadway between the dam site and the town.

### Dependable Yield

The dependable yield of a reservoir is usually taken to be the average draft rate which can be continuously sustained without fully emptying the reservoir. Many variables enter into a complete analysis of the dependable yield of a given reservoir.

Data presented by the SCS generalized the dependable yield as 80% of the average annual runoff from the tributary drainage area. Data presented herein utilizes storage-yield relationships developed by the Committee on Rainfall and Yield of Drainage Areas of the New England Water Works Association for the Squannacook River at Groton, Massachusetts. These relationships are contained in a progress report of the Committee, a copy of which was made available to us by the Corps of Engineers.

The yield of each reservoir was obtained by computing the storage ratio of the particular reservoir in million gallons of volume per square mile of drainage area. The total water surface area on the drainage basin was then estimated. Reservoir Volume, tributery drainage area and proposed reservoir water surface area were taken from the SCS data. Existing water surfaces were estimated from USGS quadrangle maps. The curves were entered with the above data and a unit yield determined. This was multiplied by the total tributery area to determine the dependable yield of the particular reservoir.

### Reservoir Configuration

A reservoir should have a shape that will not enhance short-circuiting of incoming waters and be of such a depth that large areas of shallow flowage are not created, especially around the margins. The topography should be such that there is a high ratio of storage to dam volume.

In assaying the quality of the configuration of a proposed reservoir, this report has considered the following major factors:

- 1. Expected Raw Water Quality
- 2. Short-Circuit Potential
- 3. Proportion of Shallow Area to Total Area
- 4. Storage-Dam Volume Ratio.

Reservoir Configuration has been rated on a scale from poor (P) to fair (F) to good (G) to excellent (E) depending upon the above considerations.

### Size of Dam

The volume of fill required for each dam was taken from data made available from the SCS.

Where additional dikes were considered necessary, dike construction was included under relocation costs.

### Multi-Use Potential

In considering multi-use potentials, this report considered the following aspects:

- 1. Flood Control
- 2. Boating and Fishing
- 3. Accessibility
- 4. Proximity to Population Centers.

Multi-Use Potentials have been rated on a scale from <u>limited</u> or <u>low</u> (L) to fair (F) to good (G) to excellent (E).

### Water Quality

Water quality has been reported by the New Hampshire Water Supply and Pollution Control Commission in Staff Report No. 67, Piscataqua River and Coastal New Hampshire Basins Water Quality Management Plan. In that report the existing water quality and classifications of surface waters were presented.

Four general descriptions were used for existing water quality. These were Classes C and D of the state river water quality classification system, suspected or unconfirmed man produced pollution, and no known man-produced pollution. In those areas where monitoring data was not available or considered out of date, no existing water quality was noted.

For the purposes of this report, existing water quality, where classified, has been reported according to the finding. Areas of "suspected pollution" were considered as "poor" (P). Areas of "no known pollution" were considered "good" (G). Areas where no classification has been made were reported as "none" (N).

Future water quality classification is generally planned to be Class B. Certain areas are planned to be Class A. These classifications have been used in the presentation.

### Relocations

The length of roadways, utilities and railroads requiring relocation was determined from field and map measurements. The portions considered for relocation were the lengths deemed necessary to be rebuilt to protect against flooding and to provide reasonable approaches.

### Appurtenant Facilities

Appurtenant facilities were considered to be those structures not normally considered when assessing a given dam site for construction. Such structures would include dikes, diversions, and other similar specialty items.

For the purpose of this study, dikes have been the only appurtenant facilities considered. The number and extent of diking have been reviewed in relation to the magnitude of the reservoir, and have been rated on a scale from low (L) to some (S) to high (H) to major (M) considerations.

### Site Conditions

In assessing site conditions, this report has considered the following aspects:

- 1. Soil Characteristics
- 2. Valley Shape
- 3. Spillway Layout
- 4. Extent of Swamps and Swales.

Site conditions have been rated on a scale from poor (P) to fair (F) to good (G) to excellent (E).

### Area Inundated

The amount of inundation was taken from data made available from the SCS. The area considered was the extent of the maximum flood pool.

### Downstream and Upstream Impacts

Downstream and upstream impacts were taken as the amount of disruption which would be caused by the retention of water in the proposed reservoir. The factors considered affected were only those which were obvious from the on-site inspections.

By necessity, the degree of impact of a given reservoir has been made in a qualitative manner using best engineering judgement with available data. Downstream impacts have been rated on a scale from low (L) to some (S) to high (H) to major (M) considerations. Upstream impacts were rated from none (N) to limited (L) to high (H) to major (M).

### Costs

Costs of construction for each reservoir have been estimated. The estimates have been separated into two categories: costs associated with the construction of the dam and reservoir and costs associated with the taking of structures and relocation of facilities as a consequence of the impoundment of water.

Cost of embankment and reservoir construction were estimated using curves presented in Appendix F, Upstream Flood Prevention ad Water Management, of the North Atlantic Regional Water Resources Study. The curves present unit costs of construction versus the volume of earth fill and costs of installation services as a percentage of construction cost. The construction cost includes the cost for earth fill, concrete, piping, gates, drains, spillway, etc. Installation services include geologic investigations, surveys, engineering, construction supervision and inspection and administrative overhead.

The cost data presented in the NAR study had been updated to 1970 from PL.566 as built construction costs. For use in this study the curves were advanced to an Engineering News Record Construction Cost Index of 2600. The resulting curves for determining unit embankment costs (Figure 2) and percent cost for installation services (Figure 3) are presented herein.

From the data furnished by the SCS, it was found that the unit cost curve

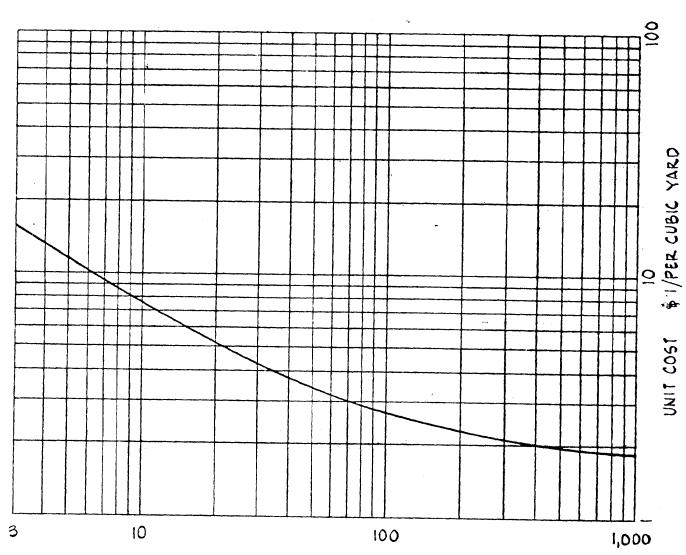

UNIT EMBANKMENT COST.

VOLUME - 1000 CUBIC YARDS

INSTALLATION COST
V5.
EMBANKMENT COST
HAYDEN, HARDING & BUCHANAN INC.
BOSTON, MASS.

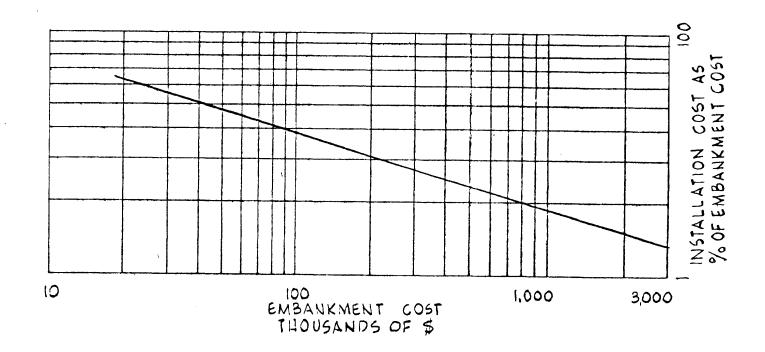

FIGURE 3 ENR = 2000 SEPT. 1977

had not included cost for clearing of the permanent pool. The data further indicated that the 1970 cost for clearing was \$400 per acre. Advancing the estimated clearing cost for an ENR Index of 2600, resulted in a unit value of \$750 per acre. The area used in the cost computation has been the area of the beneficial pool.

Installation costs have been assumed to have maintained the same percentage relationship to total cost as was the case in the NAR Study. Consequently no change in the position of the installation cost curve was made, however, the curve was extended to cover a wider range.

The costs associated with the taking of structures and relocation of facilities were determined from our on-site survey. Each building or building group was analyzed and an estimate made of the approximate fair market value. Factors were included for land or other real property. Costs of relocation were estimated on the basis of duplication of the existing unit above the reservoir inundation.

Annual payments have been calculated from the total fixed costs estimated. The basis for payments determination has been an amortization over 50 years at 6-5/8% interest.

### Social Aspects

The degree of disruption of social aspects caused through roadway and utility relocations or abandonment, allocation of flows with competing water use, inundation of cultural features, and the problems created by the actual dam construction, have been analyzed on a qualitative basis. Disruption of cultural features and relocations from roadways and utilities have been rated on a scale ranging from none (N) to limited or low (L) to some (S) to high (H)

to major (M) disruptions. Competing water usage has been rated on a none-low-some-major (N,L,S,M) scale while the impact of construction was rated on a low-some-high (L,S,H) scale.

The number of homes, businesses, barns and cemeteries within the reservoir area have been assessed individually and enumerated. The reservoir area has been taken as 300 feet horizontally beyond the high water mark. All structures within this taking limit have been considered. Cemeteries, however, were only considered when they were within the inundated area. The affect on these units have been given a dollar value as described above for relocation costs.

### RESERVOIR DESCRIPTIONS

Since the reservoirs investigated under this study vary considerably in size, location and configuration, no attempt has been made to generalize the data pertaining to them. Further, the reservoirs have been analyzed and considered separately. For these reasons, a description of each reservoir has been prepared as a separate dissertation of the conditions found or data made available concerning each particular reservoir.

DESCRIPTIO	N:	•		•	<del></del>

The reservoir site is in an undeveloped area of mixed forest and swamp. The valley narrows at the proposed dam site.

There is a railroad line running through the proposed reservoir site. Approximately 2.4 miles would be within the reservoir but a total of 4.5 miles would be relocated to permit acceptable grades.

There were several homes under construction above the reservoir on the drainage area but no apparent major pollution or water users either above or below the reservoir.

Soils in the area were generally stoney and appeared fairly impervious.

The distance to Sanbornville (Wakefield) is 2.5 miles.

DESCRIPTIO	NI •					

The reservoir area is primarily a mixed forest with some fields. Two roads in the upper part of the reservoir would require raising or abandoning. Although a cemetery is shown on the USGS map to be within the inundation, this cemetery was not seen during the on site inspection.

The reservoir site is a wide, deep valley, narrowing to the proposed dam site. Soils in the area appear gravelly and well drained.

An alternate dam site located about 3/4 mile downstream appears also feasible. If a lower water surface were used for either site, the amount of relocation could be reduced or eliminated. There would be some reduction in storage volume due to the lower embankment, but also a corresponding reduction in dam volume and cost.

The distance to Milton is 4.0 miles.

### DESCRIPTION:

The reservoir area is mixed forest with some fields. The site is fairly broad and provides shallow reservoir. The dam site is fairly wide in relation to the reservoir area.

There is a new private dirt road at the southern end of the dam site. Electric power has been installed on the roadway. Although no confirmation could be made during the onsite inspection, it is assumed that a portion of the road will be relocated.

The distance to Sanbornville (Wakefield) is 2.5 miles.
